

Weir Systems (/initiative/4Xx3/weir-systems)

The survival of fish populations often depends upon making stream water slightly deeper in specific places at specific times. Deeper water protects fish from predation, facilitates crucial migrations, and beneficially cools the water. This proposal would create a boom in fish populations by raising the water depth by a few inches or feet in crucial segments of streams at times of year crucial for fish. The program would be administered by fish biologists using inexpensive computer-controlled weirs.
